

Project Overview

This project focuses on performing a detailed Exploratory Data Analysis (EDA) on the Hotstar Movies and TV Shows dataset to understand the platform's content landscape. The analysis covers data cleaning, transformation, and visualization to extract valuable insights about content categories, runtime patterns, genres, language distribution, and structural trends.

The dataset contains 6,874 entries with metadata such as title, description, genre, release year, age rating, runtime, number of seasons, episodes, and content type (Movie or TV Show). Since the data includes missing and inconsistent values, preprocessing steps were performed to clean numeric fields (like runtime), handle null values, and format columns for meaningful analysis.

Multiple visualizations were created using Python (Pandas, Matplotlib, and Seaborn) to understand:

- Distribution of Movies vs TV Shows
- Language-wise content volume
- Genre dominance
- Runtime distribution across content types (Boxplot)
- Identification of the Top 10 longest movies
- Trends across years and age ratings

This analysis highlights key patterns such as which categories dominate the platform, how runtimes vary between movies and shows, and the diversity of genres available. These insights can help in improving content strategy, user recommendations, and understanding platform behavior from a data-driven perspective.

Overall, this EDA project provides a clear, structured, and visually rich breakdown of Hotstar's content library, demonstrating strong skills in data cleaning, visualization, statistical observation, and storytelling through data.
